

ABSTRACT

A passive infra-red detector including at least three sub-detectors,
5 each sub-detector being operative to receive infra-red radiation from a corresponding
one of at least three sub fields-of-view, each sub field-of-view being exclusively defined
by an optical element which does not define any other sub field of view, the sub fields-
of-view being angled with respect to each other, adjacent ones of the sub fields-of-view
being separated by a gap of no more than 30 degrees and at least one of the sub fields-
10 of-view having at least one of the following characteristics: extending over no more
than 45 degrees in azimuth; and including not more than three azimuthally distributed
detection zones, and signal processing circuitry, operative to receive output signals from
the sub detectors and to provide a motion detection output.
